

The International Olympic Committee (IOC) Consensus Statement on Periodic Health Evaluation of Elite Athletes: March 2009

INTRODUCTION

The Olympic Games is the largest sport event in the world. In Beijing, 10500 athletes competed, selected from a large group of elite athletes in 204 countries. Sports participation on the elite level, aside from winning medals, fame and other rewards, is also important from a health perspective. There is no longer any doubt that regular physical activity reduces the risk of premature mortality in general, and of coronary heart disease, hypertension, colon cancer, obesity, and diabetes mellitus in particular. The question is whether the health benefits of sports participation outweigh the risk of injury and long-term disability, especially in high-level athletes. Sarna et al (2000) have studied the incidence of chronic disease and life expectancy of former male world-class athletes from Finland in endurance sports, power sports and team sports. The overall life expectancy was longer in the high-level athlete compared to a reference group (75.6 versus 69.9 years). The same group also showed that the rate of hospitalization later in life was lower for endurance sports and power sports compared to the reference group (Kujala 1996). This resulted from a lower rate of hospital care for heart disease, respiratory disease and cancer. However, the athletes were more likely to have been hospitalized for musculoskeletal disorders. Thus, the evidence suggests that although there is a general health benefit from sports participation, injuries represent a significant side effect.

One priority of the International Olympic Committee (IOC) is to protect the health of the athlete. During recent years, prevention of injuries and illnesses has been high on

the IOC agenda. During the Athens Games an injury surveillance system was applied for all team sports (Junge et al 2006). During the Beijing Games, the IOC ran, for the first time, an injury surveillance system covering all the athletes, showing a 10% incidence of injuries (Junge et al 2008). In Vancouver and London the surveillance system will include disease conditions as well. The surveillance studies are prerequisites for providing evidence for health development in sports as well as for developing prevention programs. Another method to decrease injuries and diseases in the elite athlete is to perform a pre-participation examination (PPE) or periodic health evaluation (PHE) of all elite athletes (Junge et al 2009). PHE in various forms have been available for many years, but a recent analysis (Wingfield et al 2004) has questioned the efficacy of PHEs in detecting serious problems in the elite athlete.

In March 2009, the IOC assembled an expert group to discuss the current state of health evaluations for athletes, aiming to provide recommendations for a practical PHE for the elite athlete, as well as to outline the need for further research. The task of the group was to review the benefits as well as potential negative effects of PHE at the elite sport level. The group did not take any position as to whether PHE should be recommended as compulsory for participation in sport. That is for the relevant sports authorities to decide.

The PHE can serve many purposes. It includes a comprehensive assessment of the athlete's current health status and risk of future injury or disease and, typically, is the entry point for medical care of the athlete. The PHE also serves as a tool for continuous health monitoring in athletes. Recent advances in this field relate to: (i) data on sudden cardiac death and other noncardiac medical problems, and the detection of risk factors and groups; (ii) a consensus conference on concussion; (iii) data on eating disorders and (iv) data on risk factors for musculoskeletal injuries. This paper addresses each of these advances in more detail after a discussion on the purpose of a PHE and the evidence we have supporting the different components of the PHE.

This statement is also being published in the *American Journal of Sports Medicine*, *British Journal of Sports Medicine*, *Clinical Journal of Sport Medicine*, *International Sports Medicine Journal* (FIMS), *Journal of Science and Medicine in Sport*, *Scandinavian Journal of Medicine and Science in Sports*, and *South African Journal of Sports Medicine*. The manuscript was prepared by the authors and is printed here without editing. The contents are those of the International Olympic Committee and do not constitute the official position of the National Athletic Trainers' Association.

Purposes of the medical evaluation

In a narrow sense, the main purpose of the PHE is to screen for injuries or medical conditions that may place an athlete at risk for safe participation. Athletes may be affected by conditions that do not have overt symptoms and that can only be detected by periodic health evaluations. One example is cardiovascular abnormalities, such as hypertrophic cardiomyopathy, arrhythmogenic right ventricular cardiomyopathy or congenital coronary arteries anomalies. These are typically silent until a potentially fatal arrhythmia occurs, but may in some cases be detected through a careful cardiovascular examination.

Screening is a strategy used in a population to detect a disease in individuals without signs or symptoms of that disease. The intention is to identify pathologic conditions early, thus enabling earlier intervention and management in the hope of reducing future morbidity and mortality. Although screening may lead to an earlier diagnosis, not all screening programs have been shown to benefit the person being screened.

To ensure that screening programs confer the intended benefit, the World Health Organisation published what have become known as the Wilson-Jungner criteria for appraising a screening programme (Wilson & Jungner 1968). The main criteria are that the condition being screened for is an important health problem (depends not just on how serious the condition is, but also how common it is), that there is a detectable early stage, that treatment at an early stage is of more benefit than at a later stage and that a suitable test is available to detect disease in the early stage.

From a public health perspective, there is insufficient evidence to date to mandate any specific screening tests for elite athletes apart from those recommended for the general population. This is mainly the consequence of the low risk of serious conditions in this population. An important limitation is also the lack of suitable screening tests; such tests must be reliable (repeatable, good inter-observer agreement), sensitive (detects all those with increased risk), specific (detects only those with increased risk), affordable (ideally cheap, easy to perform, widely available), acceptable to the screening population and subject to quality assurance.

However, the PHE may serve other purposes than just screening athletes for future health problems. One obvious goal is to ensure that current health problems are managed appropriately and, ultimately, to determine whether an athlete is medically suitable to engage in a particular sport or event. Even elite athletes with easy access to medical care do not always seek medical attention for injuries or disease, despite having significant symptoms.

Some silent conditions are common and, although not severe from a health perspective, may influence sports performance. An example of this is mild iron deficiency, which is common in female athletes. Periodic health evaluations and ongoing monitoring represent an opportunity to diagnose and manage such conditions. They also provide an opportunity to identify conditions that are barriers to performance. An example is astigmatism, which can be detected on a simple test of visual acuity. Another important function of periodic health evaluations is that they allow the athlete an opportunity to establish a relationship with the health personnel who will be involved in providing continuing care.

Finally, the PHE also represents an opportunity to look for characteristics which may put the elite athlete at risk for future injury or disease. However, as mentioned above, there is limited direct evidence to suggest that it is possible to predict future outcomes based on the PHE. Nevertheless, there is evidence in some areas, such as injury risk factor assessment (Bahr & Engebretsen 2009), that holds future promise and warrants investigation related to the PHE. Depending on the sport and the age, ethnic origin and gender of the athlete, it may be prudent to include an assessment of specific risk factors in the PHE.

General requirements of a PHE

It is important to address and balance the ethical and legal aspects of the PHE in order to help protect the rights and responsibilities of athletes, physicians, sporting organizations and other persons concerned. In the context of designing and implementing a PHE, the following considerations need to be taken into account:

- PHE should be based on sound scientific and medical criteria.
- PHE should be performed in the primary interest of the athlete, that is, assessing his/her health in relation to his/her practice of a given sport.
- PHE should be performed under the responsibility of a physician trained in sports medicine, preferably by the physician responsible for providing ongoing medical care for the athlete, e.g. the team physician.
- The decision concerning the nature and scope of the PHE should take into account individual factors, such as the geographical region, the sport discipline, the level of competition, age and gender of the athlete.
- The setting of the evaluation should be chosen to optimize the accuracy of the examination and respect the privacy of the athlete. The PHE should preferably be carried out in the physician's office, which assures privacy, access to prior medical records, and an appropriate patient-physician relationship.
- A physician can only perform a PHE with the free and informed consent of the athlete and, if applicable, his/her legal guardian.
- If PHE evidences that an athlete is at serious medical risk, the physician must strongly discourage the athlete from continuing training or competing until the necessary medical measures have been taken.
- Based on such advice, it is the responsibility of the athlete to decide whether to continue training or competing.
- If a physician is requested to issue a medical certificate, he or she must have explained in advance to the athlete the reason for the PHE and its outcome, as well as the nature of information provided to the third parties. In principle, the medical certificate may only indicate the athlete's fitness or unfitness to participate in training or competition and should minimize disclosure of confidential medical information.

In many settings, the PHE is used to offer medical clearance to participate in sport and is seen as a one-time certification for future involvement in elite sport. However,

the evaluation of the athlete's health should ideally be seen as a dynamic, ongoing process.

While many aspects of the PHE will be common to all elite athletes, it should be tailored to be gender, age, race, culture and sport specific when appropriate. If any injury or medical condition is identified, it should be managed in a manner consistent with the existing standards of medical care. If warranted, this may involve referral to the appropriate specialists for further evaluation and management. It should be noted that the PHE is also the time that medications or nutritional products in use or prescribed should be reviewed to determine if a Therapeutic Use Exemption (TUE) application to the World Anti Doping Association (WADA) is needed.

The timing of the PHE should ideally allow for sufficient time for management of any injuries or medical problems well before major competitions. For example, it is preferable to conduct a PHE during the off-season so that rehabilitation or other treatment can restore the athlete to optimal health before facing maximal physical stress.

As the PHE is the only contact that many elite athletes will have with medical personnel, it should be seen as an opportunity for education regarding other health risks and health-related behavior.

The following document is laid out in sections that correspond to the various areas of evaluation appropriate to the elite athlete.

1. CARDIOLOGY

1.1 Introduction

The scope of the cardiovascular PHE is to detect potentially lethal cardiovascular disease in elite athletes and start appropriate management to reduce the risk for sudden cardiac death and/or disease progression in a timely fashion.

1.2 Evidence base

Cardiovascular (CV) risk of competitive sport participation. Regular participation in training and athletic competition is associated with an increased risk for sudden cardiac death (SCD), with an average relative risk for athletes of 2.8 times compared to their nonathletic counterpart (Corrado et al 2003). It is worthy to note, however, that sport is not per se the cause for greater incidence of SCD. It is the combination of intensive physical exercise in athletes with underlying cardiovascular disease, which can trigger ominous arrhythmias leading to cardiac arrest. The relative risk of sport participation is different according to the underlying disease, and it is greatest in case of cardiomyopathies (such as hypertrophic cardiomyopathy or arrhythmogenic right ventricular cardiomyopathy) or congenital coronary arteries anomalies (Corrado et al 2003).

Rationale for CV evaluation in elite competitive athletes. The vast majority of the athletes dying suddenly do not experience premonitory symptoms (Maron 2003); therefore, the PHE represents the only strategy capable to identify athletes with silent cardiac disease, and allow appropriate management to reduce the risk of SCD and disease progression. Identifying asymptomatic athletes with underlying cardiovascular disease through the PHE is important because SCD could be prevented by lifestyle modification, including (when necessary) restriction from

competitive sports activity, but also prophylactic treatment by drugs, implantable cardioverter defibrillator (ICD) or other therapeutic options. Athletes carrying an increased cardiac risk may have a favourable long-term outcome thanks to timely identification and appropriate clinical management (Corrado et al 1998).

Rationale for including the 12-lead Electrocardiogram (ECG) in the PHE. Recent scientific evidence supports the role of ECG in reducing mortality in screened athletes (Corrado et al 2006). This concept is based on the recognition that ECG is abnormal in most individuals with hypertrophic cardiomyopathy (up to 90%) and arrhythmogenic right ventricular cardiomyopathy (up to 80%). The ECG can also identify athletes with WPW syndrome and ion channel diseases, such as Lènegre conduction disease, long or short QT syndromes, and Brugada syndrome (Corrado et al 2007, Lawless and Best 2008). However, criticism has been voiced related to available data on the use of ECG in elite athletes due to the lack of an unscreened athletic control group. A comparison of athletes screened with ECG vs. athletes non-screened will require two matched large athlete populations (several thousand athletes, in consideration of the low incidence of cardiomyopathies) undergoing long-term follow-up (at least two decades, due to the young age of athletes at initial evaluation).

It has been demonstrated that adding a 12-lead ECG examination to history and physical examination results in a substantial increase in the ability to identify potentially lethal heart disorders (Corrado et al 2007, Lawless and Best 2008) and this strategy has been endorsed in "The Lausanne Recommendations" (Bille et al 2006) and the European Society of Cardiology recommendations (Corrado et al 2005). However, it is not currently recommended by the American Heart Association (Chaitman 2007, Myerburg and Vetter 2007).

1.3 Proposal for PHE

The following questions regarding cardiovascular abnormalities should be included:

Family history

- Family history of one or more relatives with disability or death of heart disease (sudden/unexpected) before age 50
- Family history of cardiomyopathy, coronary artery disease, Marfan syndrome, long QT syndrome, severe arrhythmias, or other disabling cardiovascular disease

Personal history

- Syncope or near-syncope
- Exertional chest pain or discomfort
- Shortness of breath or fatigue out of proportion to the degree of physical effort
- Palpitations or irregular heartbeat

Physical examination should be performed according to the best clinical care and should investigate the presence of:

- Musculoskeletal and ocular features suggestive of Marfan syndrome
- Diminished and delayed femoral artery pulses
- Mid- or end-systolic clicks

Figure 1. 12-Lead electrocardiographic abnormalities in the athlete. Abbreviations: AV, atrioventricular block; RBBB, right bundle branch block; LBBB, left bundle branch block.

- Abnormal second heart sound (single or widely split and fixed with respiration)
- Heart murmurs (systolic grade $>2/6$ and any diastolic)
- Irregular heart rhythm
- Brachial, bilateral blood pressure $>140/90$ mmHg on more than one reading

The 12-lead ECG. The 12-lead ECG should be recorded on a non-training day, during rest, according to best clinical practice. Interpretation of the ECG abnormalities can be categorized according to the criteria defined by Corrado et al (2008) into two groups: 1) the most common in trained athletes (sinus bradycardia, first degree AV block, notched QRS in V1 or incomplete right bundle branch block, isolated QRS voltage criteria for LV hypertrophy) consistent with athlete's age, ethnical origin and level of athletic conditioning, and that do not require additional testing; 2) all other less common ECG abnormalities should be further evaluated to exclude cardiovascular disease (Fig 1).

Further investigations. At present, there is no agreement regarding the need for routine use of echocardiography in the PHE. Neither is there a role for routine use of other imaging or invasive testing. However, in the presence of abnormal findings either at history, physical examination or 12-lead ECG, additional testing should be performed in order to confirm (or exclude) cardiovascular disease. In most instances, echocardiography is the first-line test, but other imaging modalities (such as cardiac magnetic resonance) or invasive testing, when necessary, may be pursued. In adult athletes (>35 years) exercise ECG testing in the context of PHE is efficient to detect otherwise unsuspected cardiac abnormalities (Sofi 2008) and is currently recommended for elite athletes with increased cardiovascular risk profile (Thompson 2007).

1.4 Management of athletes with CV abnormalities

The IOC PHE Consensus Group recommends that any athlete identified with a CV abnormality should be managed according to the current, widely accepted clinical recommendations, i.e., Bethesda Conference #36 and ESC recommendations (Maron and Zipes 2005, Pelliccia et al 2005). The group acknowledges that identification of cardiac disease in an athlete represents a challenging question regarding the ethical, medical and legal consequence with particular regard to the need for disqualification from competition. However, there is scientific evidence that preventing athletes with specific cardiovascular abnormality from regular training and competition is an efficient strategy for preventing SCD (Corrado et al 1998, Biffi et al 2004). Unnecessary exclusion from participation of competitive athletes with non lethal diseases is a problem. Therefore, there is a need for a common agreement of sports eligibility guidelines and management of competitive athletes with cardiovascular diseases in the future (Pelliccia et al 2008). The main goal should be to reduce the number of unnecessary disqualifications and to adapt (rather than restrict) sports activity in relation to the specific cardiovascular risk.

Finally, we recognize that young competitive athletes (<18 years) require specific expertise in the evaluation, interpretation of findings and management.

1.5 Educational programmes

The sport organizations together with scientific sport societies should encourage and support educational activities intended to enhance the knowledge and skill of physicians involved in the cardiology part of the PHE process.

1.6 Research

Although there are issues of debate regarding wide-scale mandatory use of the ECG for athlete screening (Chaitman 2007, Pelliccia 2008), there is sufficient evidence to justify a staged implementation with evaluation to assess the properties of the test (sensitivity, specificity, predictive value) in a variety of sporting populations. Staged implementation would provide a natural control group to measure differences in outcome between ECG screened and unscreened groups. Finally, the mortality effects of a screening program documented in Italy need to be replicated in other ethnic populations where the underlying disease conditions may differ from those seen in Italy.

The sport organizations and scientific sport societies should encourage research that could expand our current knowledge and data base regarding the mechanisms and strategies to prevent SCD in competitive athletes.

2. NON-CARDIAC MEDICAL CONDITIONS

2.1 Introduction

To date, the main elements of the PHE have been to screen elite athletes for possible risk for sudden cardiovascular death (Beckerman et al 2004, Corrado et al 2005), musculoskeletal injury (Garrick 2004), and head injury

(McCrory 2004). Furthermore, elements of the PHE that focus on non-cardiac medical conditions have to date been confined to hematological conditions (Fallon 2004), lung disease, particularly exercise-induced bronchoconstriction (Holzer and Brukner 2004), and specific medical concerns of the female athlete (Rumball and Lebrun 2004).

However, sports physicians who regularly perform medical assessments on elite athletes, as well as members of the medical team that accompany athletes to the Olympic Games and other international sports events, commonly encounter medical conditions that are non-injury related, and are of a non-cardiac nature (Derman 2003, Derman 2004, Grissom et al 2006).

In one study, it was reported that 50% of the 1804 athletes seen at the multipurpose medical facility at the 1996 Olympic Games were treated for non-injury related illnesses (Wetterhall et al 1998). In another study conducted in the athlete medical clinic during the 2002 Winter Olympic Games, medical diagnoses, notably respiratory conditions, were more commonly reported than traumatic conditions (Grissom et al 2002). Furthermore, in two other studies, over 50% of the medical consultations in a participating team during two Olympic Games were non-injury related (Derman 2003, Derman 2004). It is important to note that the frequency of cardiac-related medical consultations reported in these two studies was very low (Derman 2003, Derman 2004).

Therefore, medical conditions in systems other than the cardiovascular system are very common in elite athletes. These conditions can occur immediately before competitions, during periods of training in preparation for competitions, and after competitions. In two reports, the frequency of medical conditions reported in athletes during the Olympic Games has been documented (Table 1). These data indicate that medical conditions, other than cardiovascular conditions, are common in elite athletes, yet these conditions have not received much attention in a PHE. A spectrum of medical conditions can occur in athletes across a number of medical systems (Table 2) and these can be identified during a PHE (Rifat et al 1995, Lively 1999). Finally, a number of these conditions are transient and can be treated. Therefore, clearance for sports participation when athletes suffer from these conditions is an ongoing process and requires ongoing monitoring and assessment.

The purpose of this section is to 1) briefly review the evidence base for including elements in the PHE that focus on non-cardiac medical conditions, 2) recommend elements in the medical history, physical examination and special investigations that could be included in a PHE to identify significant non-cardiac medical conditions, and 3) suggest future directions for research in this area.

2.2 Evidence base: Non-cardiac medical conditions

There is very little data available on the inclusion of assessment for non-cardiac medical conditions in a PHE. Evidence for the inclusion of screening tests to identify non-cardiac medical conditions in a PHE is therefore largely limited to expert opinion and case series. However, the identification of some non-cardiac medical conditions is frequently included in the medical history, physical examination and profile of special investigations of existing PHE recommendations (Joy et al 2004, Batt et al 2004, Brukner et

Table 1. Frequency (% of All Formal Medical Consultations) of Medical Consultations at the Olympic Games in a Team

	Sydney 2000 Olympic Games	Athens 2004 Olympic Games
Ear, nose, and throat (ENT)	18	13
Pulmonary (Respiratory)	16	8
Nervous system (neurological)	16	4
Gastro-intestinal	6	6
Dermatological	2.5	16
Urological	2.5	0
Psychological/Psychiatric	2	3
Cardiology	1	3
Ophthalmological	0.5	0.5
Other	4.5	6

al 2004, Fuller et al 2007, Constantini and Mann 2005, Nichols et al 1995). The evidence base for including screening to identify non-cardiac medical conditions in a PPE will be briefly reviewed below.

2.2.1 Pulmonary system. The rationale for including an assessment of the pulmonary system in a PHE is that respiratory symptoms that are suggestive of asthma are common in athletes (Fitch et al 2008). At the time of a PHE, these symptoms can be identified, and the clinical examination, together with objective special tests can be used to confirm the diagnosis of asthma (Fitch et al 2008). The prevalence of asthma in athletes is high and varies from 3–23% in summer sports to 12–50% in winter sports (Carlsen et al 2008, Cummiskey et al 2008). Furthermore, during a PHE, respiratory tract conditions other than asthma that can also give rise to respiratory symptoms in athletes can be identified (Cummiskey et al 2008).

2.2.2 Hematological. The main rationale for including routine hematological assessment during a PHE is based on the higher than expected prevalence of decreased iron stores in athletes, particularly female athletes (Fallon 2004, Gropper et al 2006, Sinclair and Hinton 2005, Fallon 2007, Eliakim et al 2002, Rietjens et al 2002, Di Santolo et al 2008). An additional rationale is to determine if the athlete has anemia (iron deficiency or other), and to identify other illnesses such as infections (Fallon 2004). It is noteworthy that hematological testing has been suggested as a screening/monitoring tool for blood doping (hematological passport) as well (Schumacher et al 2002). The likelihood of a positive result on routine hematological screening is higher in physically active females compared with male athletes (Fallon 2004, Fallon 2007, Dubnov et al 2006).

2.2.3 Allergies. The rationale for including assessments in the PHE to identify allergies, particularly allergic rhinoconjunctivitis, in elite athletes is based on the fact that 1) significantly higher than expected prevalence of allergic conditions has been observed in elite athletes (Katelaris et al 2006, Katelaris et al 2000, Katelaris 2001, Hawarden et al 2002); 2) travelling athletes could be exposed to a variety of allergens at different venues where international competitions take place (Katelaris et al 2000); and 3) acute and chronic allergies could result in morbidity and also reduce athletic performance (Katelaris et al 2003).

2.2.4 Infections and immunological. The rationale to consider infective disease in a PHE is based on a number of important considerations. Firstly, it is established that during intense training and immediately following competitions, there is evidence of immune suppression in athletes

Table 2. Non-Cardiac Systems That Should Be Considered in a Periodic Health Evaluation

Pulmonary
Haematological
Allergies
Infections and immunological
Ear, nose, and throat (ENT)
Dermatological
Urological and genital
Gastro-intestinal
Nervous system (neurological)
Endocrine/metabolic
Psychological/Psychiatric

that could predispose them to infective disease (Gleeson 2006, Ekblom et al 2006). Secondly, acute systemic infective illness is a contra-indication to participation in sports because of the risk of viral myocarditis, organ injury (splenomegaly) and in some cases increased risk of transmission of the infective illness to fellow athletes (Schwellnus et al 2008, Luke and d'Hemecourt 2007, Pirozzolo and McMay 2007). Thirdly, the PHE provides an opportunity to assess whether an athlete has been immunized against infective conditions, including those that may be associated with international travel to specific regions. There are a number of infective illnesses that could be considered when performing a PHE and these have been reviewed recently (Schwellnus et al 2008, Luke and d'Hemecourt 2007).

2.2.5 Ear, nose and throat (ENT). The rationale for including the ear, nose and throat (ENT) assessment in a PHE is based on the high incidence medical consultations during international competitions that are related to this system in elite athletes (Table 1). Furthermore, the common illnesses encountered in the ENT system of athletes are allergies (Katelaris et al 2006, Katelaris et al 2003) and upper respiratory tract infections (Grissom et al 2002, Ekblom et al 2006, Schwellnus et al 2008, Malm 2006). The basis for including this spectrum of conditions in PHE has already been discussed.

2.2.6 Dermatological. The rationale for including a dermatological assessment in the PHE is that skin disorders are very common in athletes (Adams 2008, Adams 2002, Adams 2003). Furthermore, participation in sports may predispose athletes to certain skin conditions and there is a risk of transmission of certain skin conditions during sports (Adams 2008). Therefore, clearance to compete may have to be withheld temporarily if athletes suffer from some skin infections (Adams 2008).

2.2.7 Urological. The rationale for including an assessment of the urological system in the PHE is not based on strong evidence. However, it is known that 1) renal and bladder disease can be asymptomatic; and 2) conditions such as asymptomatic haematuria, proteinuria and pyuria are often encountered when screening in athletes is conducted (Rayner and Schwellnus 2008). Although these conditions may not be clinically significant, they do however require further evaluation to exclude underlying urological disease.

2.2.8 Gastro-intestinal (GIT). The rationale for including an assessment of the gastro-intestinal (GIT) system in the PHE is that GIT symptoms are very common in athletes (particularly endurance athletes) during sports participa-

tion (Schwellnus and Wright 2008). Exclusion of significant underlying GIT disease is therefore important in athletes, particularly those that regularly suffer from GIT symptoms during exercise (Schwellnus and Wright 2008). Furthermore, GIT conditions are also frequently encountered when travelling with athletes to international competitions (Derman 2003, Derman 2004).

2.2.9 Nervous system (neurological). The rationale for including assessment of neurological conditions in the PHE of athletes is that neurological conditions are common (McCrory 2008) and can include a variety of different conditions such as headaches and epilepsy. Furthermore, although uncommon, stroke can occur in younger adults, including athletes. It has been suggested that the PHE should include screening for the risk factors of stroke in young athletes (McCrory 2008).

2.2.10 Endocrine/metabolic. The rationale for routine enquiry to determine if elite athletes have underlying endocrine and metabolic disease is 1) that these conditions do occur in elite athletes; 2) one of the more common endocrine conditions in elite athletes is diabetes mellitus - nine Olympic athletes required therapeutic use exemption for the use of insulin in the 2004 Summer Olympic Games (Tsitsimpikou et al 2009); and 3) elite athletes with existing endocrine and metabolic disease may require counseling and advice because medication they may use could contravene doping control regulations (Anderson et al 2008).

2.2.11 Ophthalmology. The principle rationale for including ophthalmological assessment in the PHE is that ophthalmic conditions, particularly reduced visual acuity, have been reported in 4.5–25% of college athletes undergoing a PHE (Rifat et al 1995, Lively 1999, Carek and Mainous 2003). Other less common ophthalmological conditions can also be identified.

2.3 Proposal for content of the PHE

Assessment of non-cardiac medical conditions during a PHE would include an appropriate systematic medical history (Table 3). A directed physical examination and selected special investigations (Table 4) should follow. Routine investigations that are recommended are 1) urinalysis (males and females) and 2) tests for iron stores (female athletes). According to best medical practice guidelines, these elements should be included in the PHE to assess elite athletes for the presence of non-cardiac medical conditions.

2.4 Possible future directions in research

Broad research areas:

- Defining the scope of the problem in each system (prevalence of non-cardiac medical conditions in elite athletes)
- Determining the impact of these medical conditions on performance, short term risk, and longer term outcome in elite athletes
- Investigate which diagnostic tests have the highest sensitivity, specificity and predictive value for each condition
- Determine if identification and management of these conditions reduces morbidity and improves performance in elite athletes

Table 3. A List Of Suggested Questions in the Medical History to Identify Non-Cardiac Conditions in a Periodic Health Evaluation

Suggested question/s in the medical history *	
Pulmonary system	Do you have a past history or currently suffer from any symptoms of respiratory (lung) disease including asthma, wheezing, cough, postnasal drip, hay fever, or repeated flu like illness?
Hematological system	Do you have a past history or currently suffer from any symptoms of disease of the blood system including low iron stores, anemia, (in particular iron deficiency anemia)?
Allergies	Do you have a past history or currently suffer from any symptoms of allergies including allergies to pollen, foods, medication, any plant material or any animal material?
Infection/immunological	Do you have a past history or currently suffer from any symptoms of disease of the immune system including current infections, recurrent infections, HIV/AIDS, leukemia, or are you using any immunosuppressive medication?
Ear, nose, and throat (ENT)	Do you have a past history or currently suffer from any symptoms of disease of the ears (infections, hearing loss, pain), nose (sneezing, itchy nose, sinusitis, blocked nose) or throat (sore throat, hoarse voice, swollen glands in the neck)?
Dermatological	Do you have a past history or currently suffer from any symptoms of skin disease including skin rashes, skin infections, itchy skin, allergies, or skin cancer?
Urological	Do you have a past history or currently suffer from any symptoms of disease of the kidney or bladder including past history of kidney or bladder disease, blood in the urine, loin pain, kidney stones, frequent urination, or burning during urination?
Gastro-intestinal	Do you have a past history or currently suffer from any symptoms of gastrointestinal disease including heartburn, nausea, vomiting, abdominal pain, weight loss or gain (>5 kg), a change in bowel habits, chronic diarrhea, blood in the stools, or past history of liver, pancreatic or gallbladder disease?
Neurological	Do you have a past history or currently suffer from any symptoms of diseases of the nervous system including past history of stroke or transient ischaemic attack (TIA), frequent headaches, dizziness, blackouts, epilepsy, depression, anxiety attacks, muscle weakness, nerve tingling, loss of sensation, muscle cramps, or chronic fatigue?
Endocrine/metabolic	Do you have a past history or currently suffer from any symptoms of metabolic or hormonal disease including diabetes mellitus, thyroid gland disorders, hypoglycemia (low blood sugar), or heat intolerance?
Ophthalmological	Do you have a past history or currently suffer from any symptoms of eye disease or injury including decreased vision, pain in the eyes, itchy eyes, increased or decreased tear production, discharge from the eye or red eyes?

* If the answer to any of these questions is YES, further details and directed in-depth assessment is required.

3. CONCUSSION IN SPORT

3.1 Introduction

Concussion in sport is defined as a complex pathophysiological process affecting the brain, induced by traumatic biomechanical forces (Aubry et al 2002).

Estimates in the United States range from 1.6 to 3.8 million concussions per year related to sport and recreation (Langois 2006 and Centers for Disease Control and Prevention 2007). There is evidence that concussions are particularly prevalent in collision sport (Browne 2000, Guskiewicz 2006).

Table 4. Key Elements in the Physical Examination for Non-Cardiac Conditions in a Periodic Health Evaluation

Selected key components in the physical examination*	
Pulmonary system	Comprehensive examination including assessment of chest including percussion, and auscultation
Hematological system	Comprehensive examination including assessment for pallor, and evidence of infections
Allergies	Comprehensive examination for manifestations of acute and chronic allergy
Infection/immunological	Comprehensive examination for lymphadenopathy, splenomegaly
Ear, nose, and throat (ENT)	Comprehensive examination including external auditory canal, tympanic membrane, sinus tenderness, nasal septum, turbinate bones, oropharynx, tonsils, indirect laryngoscopy (if indicated), cervical and regional lymphadenopathy
Dermatological	Comprehensive examination of sun exposed areas, assessment of skin infections (fungal)
Urological	Comprehensive examination including assessment for suprapubic tenderness, abdominal examination for renal masses, genital examination (males)
Gastro-intestinal	Comprehensive abdominal examination for including assessment for abdominal tenderness, organomegaly, and hernias
Neurological	Comprehensive examination including assessment of cranial nerve function, motor function, sensory function, reflexes, and the extrapyramidal system
Endocrine/metabolic	Comprehensive examination including assessment for the complications of diabetes mellitus, and the clinical signs of thyroid disease
Ophthalmological	Comprehensive examination including assessment of visual acuity, visual fields, infective and allergic eye disease, funduscopy

* a) The list of suggested physical signs is not intended to be comprehensive but to serve as a guideline

b) If a positive finding is identified, further in-depth assessment with appropriate special investigations is required

3.2 Evidence base

The IOC and several members of the present consensus group participated in the recent Zurich Consensus Statement on Concussion in Sport (McCrory et al 2009) and endorse its concepts and principles. A structured consensus-development conference format was used, modelled after the protocol of the National Institutes of Health, including development of evidence-based recommendations. The specific evidence and rationale are provided in detail in the manuscript by McCrory et al 2009.

3.3 Proposal for content of the PHE

It is recognized that a structured concussion history is an important component of the PHE, and should include specific questions regarding:

- previous symptoms of a concussion; not just the perceived number of past concussions; appreciating the fact that many athletes will not recognize all the concussions they may have suffered in the past
- all previous head, orofacial or cervical spine injuries
- whether repeated concussions produce disproportionate severity of symptoms given the amount of impact; alerting the clinician to a progressively increasing vulnerability to injury
- use of protective equipment such as helmets, facial protection and mouth guards; including their age and state of repair
- the ability of the athlete to adopt protective behavior such as avoiding overly aggressive or high risk situations

The purpose in obtaining such a history may identify athletes that fit into a high risk category and provides an opportunity for the healthcare provider to educate the athlete in regard to the significance of concussive injury.

3.4 Possible future directions for concussion in sport

The Concussion in Sport Group (McCrory et al 2009) had extensive discussion and general agreement on the principle of doing baseline assessment (neuropsychological, balance, etc) during the PHE in high risk sports. The intent is to provide a comparison point for possible future post injury testing. While a specific recommendation for baseline examination in the PHE was not included in the concussion consensus document, one of the suggested future directions in research was the “clinical assessment where no baseline assessment has been performed” (McCrory et al 2009).

4. DENTAL INJURIES

4.1 Introduction

Oral health evaluation has significant relevance to the establishment of an improvement in oral health. Good oral health will ensure good function and the ability of the athlete to compete at an optimal level without being compromised by dental disease or an otherwise preventable emergency.

4.2 Evidence base

Statistics collected by the IOC at recent summer games (Fasel 2008) have highlighted the level of dental disease in

many participants. The use of a DMF Index (“decayed-missing-filled” a dental screening tool) and appropriate radiographs to measure dental disease may also identify oral health behavior and the extent of poor oral health prevalent in our elite athlete group (Levin et al 2004, WHO 4th ed. 1997; 40–7). The identification of erosion, the prevalence of which is estimated to be 25.4–37.4% in athletes, may be an indicator of excessive use of sports beverages, which are acidic in nature (Sirimaharaj et al 2008, Vasan 1998). In addition, erosion may be caused by acidic reflux, which may be indicative of an underlying eating disorder (Milosevic 1999).

The presence of wisdom teeth (Fuselier et al 2002, Yamada et al 1998) and certain malocclusions are risk factors for future injury (Kvittem et al 1998, Burden 1995). The presence or absence of wisdom teeth may affect the risk profile for mandibular fracture in combative sports (Andrade et al 2007, Ma’aita et al 2000, Schwimmer et al 1983). Additionally, associated pericoronitis and periodontal infection may affect athlete performance (Kerr 1983).

4.3 Proposal for content of the PHE

The physical examination should include the following elements:

- DMF; which is an acronym for decayed, missing and filled teeth. These three elements together with recent dental history can be used as an indicator for underlying oral health.

Other risk factors for orofacial injury that can be targeted for prevention are:

- Malocclusion where the overjet (overlap of upper over lower incisors) is greater than 6 mm (Kvittem et al 1998, Burden 1995).
- Presence of braces or orthodontic appliances (Croll et al 1996).

4.4 Possible future directions in oral health

Efforts should be made to educate athletes and authorities about the considerable benefits in preventing dental injuries by providing custom made mouthguards for those taking part in “at risk” sports (e.g. collision and contact sports)(Andrade et al 2008), and to continue to measure or quantify the benefits. Additionally, further studies are required to assess more accurately the oral health of the athlete population and educational programs should be expanded and targeted to those sports where the risks identified above influence athlete health (Cornwell 2005, Badel et al 2007). The IOC group encourages athletes to be provided with regular dental examinations.

5. MUSCULOSKELETAL INJURIES

5.1 Introduction

Musculoskeletal injuries are common in sports. Acute injuries are most common in sports in which the speed is high and the risk of falling is great (e.g. downhill skiing) and in team sports where there is significant contact between players (e.g. ice hockey and soccer). Overuse

injuries make up the large portion of injuries in aerobic sports that require long training sessions with repetitive motion (e.g. long-distance running, cycling or cross-country skiing). However, a large number of overuse injuries also occur in technical sports, in which the same movement is repeated numerous times (e.g. tennis, javelin throwing, weightlifting and high jumping). The injury profile also varies from sport to sport; each sport has its distinctive injury pattern. This pattern must be considered carefully when designing the musculoskeletal component of the PHE. The practitioner must be familiar with the most common injury types associated with the sport in question and the examination should be targeted on these injury types and their risk factors.

The main objective of the musculoskeletal PHE is to detect current injuries and ensure that these are managed appropriately. While an injured athlete may have gone through rehabilitation in the middle of the season, focus is often on return to play, sometimes using taping and bracing to protect from further injury. The off-season should be used as an opportunity to get the athlete back to full fitness. Therefore, the best timing of the PHE may be the immediate post-season (while there is still time to work on problems that are identified) rather than the pre-season.

A previous injury is the most consistent risk factor for new recurrent injuries. This has been demonstrated for a number of different injury types, such as ankle sprains, muscle strains and knee ligament injuries. A previous injury could compromise joint function through reduced mechanical stability or neuromuscular control, or muscle function through scar tissue formation, reduced strength, or more subtle changes in the length-tension relationship. It follows then, that training programs to restore strength and neuromuscular control can help prevent recurrent injuries. One important aim of the musculoskeletal PHE is therefore to identify sequelae or deficits resulting from previous injuries.

Ideally, the musculoskeletal PHE should be used to identify athletes at risk for injury. However, although a number of risk factors have been identified which makes an athlete susceptible to different injuries, the examination needs to be focused on the characteristics and requirements of the sport in question. A complete review of risk factors associated with injuries to the different body regions can be found in the IOC Handbook on Sports Injury Prevention (Bahr & Engebretsen 2009).

5.2 Evidence base

The evidence base for designing a musculoskeletal PHE to detect risk factors for future injury is limited. Players with a history of previous injury or symptoms indicating reduced function are a group with an increased injury risk that should be targeted for soft tissue examinations and with specific prevention programs addressing their deficits. However, in the asymptomatic athlete with no history of previous injury, there is limited evidence to prescribe specific tests – even using more advanced functional tests – to identify athletes at risk. One limitation is that the reproducibility of such tests is often low. Another is that the predictive value of such tests is for the most part unknown.

5.3 Proposal for the content of the PHE

The fundamental element of the musculoskeletal PHE is obtaining a thorough history of current and previous musculoskeletal injuries. To improve the history, one can use self-report forms; these should go in detail for the regions and injury types associated with the sport in question to ensure that no injuries and symptoms are missed. The clinical examination should follow up on any symptoms or injuries reported, consisting of inspection, palpation, range of motion, strength and laxity exams, effusions, muscle testing and relevant functional exams. Additional imaging (e.g. ultrasound, MRI) or more advanced functional tests (e.g. strength tests, balance tests) may be indicated based on history and physical examination.

5.4 Possible future research directions

Large-scale population-based studies are needed to evaluate the components of history and examination that can be used to identify athletes at risk, intervene and change outcome.

6. PHE ISSUES SPECIFIC TO WOMEN

6.1 Introduction

Female athlete participation in sport has increased tremendously with 42% of the athletes at the Beijing Olympic Games being female (International Olympic Committee 2008). Despite the well-documented health benefits of exercise, there are two medical conditions unique to the female athlete that may have long-term consequences that can be avoided through early detection and treatment. Low energy availability from caloric intake inadequate to meet the energy requirements of exercise can lead to secondary menstrual disorders and low bone density. This is referred to as the female athlete triad (Nattiv et al 2007). In addition, iron deficiency anemia is more common in the female athlete (Peeling et al 2008). The health and performance consequences of these two conditions can be prevented through early detection and treatment. The PHE provides a unique opportunity for the team physician to detect and treat low energy availability, menstrual disorders, low bone density and iron deficiency anemia.

6.2 Evidence base

The prevalence of eating disorders (anorexia nervosa (AN), bulimia nervosa (BN), anorexia athletica (AA), and eating disorders not otherwise specified (ED-NOS)) in the sport population was found to be 15–31% in comparison with 5–13% in the general population. The prevalence in males is generally lower than in females (Sundgot-Borgen and Torstveit 2004, Byrne and McLean 2002). The sports at highest risks are the aesthetic sports that emphasize thinness, endurance sports and weight class sports (Sundgot-Borgen and Torstveit 2004). The prevalence of secondary amenorrhea varies widely depending on the type of sport and is reported as high as 65% in long distance runners (Dusek 2001) in comparison to 2–5% in the general population (Bachmann and Kemmann 1982). The incidence of secondary amenorrhea increases with

Table 5. Dietary Restraint Questions (EDE-Q) Correlated With Low Bone Mineral Density in High School Endurance Runners

1. Have you been consciously trying to restrict the amount of food you eat to influence your shape or weight?
2. Have you gone for long periods of time (8 hours or more) without eating anything in order to influence your shape or weight?
3. Have you attempted to avoid eating any foods that you like in order to influence your shape or weight?
4. Have you attempted to follow definite rules regarding your eating in order to influence your shape or weight; for example, a calorie limit, a set amount of food, or, rules about what or when you should eat?
5. Have you had a definite desire for your stomach to feel empty?

weekly mileage (Sanborn et al 1982), with athletes in sports emphasizing leanness (Torstveit and Sundgot-Borgen 2005) and in athletes less than 15 years of age (Baker et al 1981). The incidence of primary amenorrhea is 22% in cheerleading, diving and gymnastics (Beals and Manore 2002) in comparison to <1% in the general population (Chumlea et al 2003). Likewise, the frequency of low bone mineral density in athletes is two to four times greater than the general population (Khan et al 2002). Stress fractures occur more frequently in athletes with abnormal menstrual cycles and low bone mineral density (Bennell et al 1999). Short and long term consequences of the female athlete triad are well documented in the literature and effective treatment exists (Nattiv et al 2007).

For the detection of eating disorders and disordered eating, several validated screening tools exist: the Eating Disorder Examination Questionnaire (EDE-Q) (Carter et al 2001, Passi et al 2003, Wolk et al 2005), the SCOFF Questionnaire (Luck et al 2002, Morgan et al 1999) and the Eating Disorder Screen for Primary Care (ESP) (Cotton et al 2003). A comparative study of the SCOFF and ESP screening tools by Cotton et al. identified four questions that could serve as positive predictors and two as negative predictors of disordered eating (see table included in Appendix 1 PHE Form) (Cotton et al 2003). A population of high school endurance runners with low bone mineral density was found to score higher on the EDE-Q subscale of Dietary Restraint in comparison with other subscales. The validated questions correlating caloric restriction and low bone mineral density are shown in Table 5 (Barrack et al 2008).

6.3 Proposal for content for the PHE

The history and physical examination of the female athlete should address each component of the female athlete triad. Validated questions to detect eating disorders and disordered eating should be utilized (Table 5). Assessment of menstrual pattern and a history of stress fractures should be included. A systems review may identify body systems affected by low energy availability. If so, completion of a nutritional analysis identifies the athlete at risk for energy imbalance and iron deficiency.

A physical examination should include a body mass index. The following physical signs can be found in advanced cases of eating disorders but are likely to be absent in early detection; lanugo, petechiae, subconjunctival haemorrhages, swelling of the parotid glands, erosion of tooth enamel, bradycardia, peripheral edema. A complete gynecological examination is recommended in the athlete with primary or secondary amenorrhea.

The laboratory examination should include a CBC for all female athletes and a serum ferritin for those athletes in endurance sports. For those athletes identified at risk for the female athlete triad based on a screening questionnaire, physical examination abnormalities and initial blood work, measurement of body composition is recommended. For

these athletes, laboratory tests include a hormonal screen (TSH, LH, FSH, estradiol, prolactin, Beta HCG, Testosterone, 17-OH -Progesterone, Sex Hormone Binding Capacity, Cortisol, DHEA-S, Androstenedione), CBC, biochemistry screen, bone mineral density (iDXA scan) to assess bone health, ECG to rule out electro conductive abnormalities from electrolyte disturbance in eating disorders and a nutritional analysis to assess energy balance.

6.4 Future direction

6.4.1 Research. Further research should be directed toward ascertaining the cause-effect relationship between the female athlete triad and sports participation. Validating the questions for detecting the triad is essential for accurate diagnosis and for earlier identification of athletes who would benefit from intervention. Further research into the relationship between low ferritin as a premonitor of iron deficiency anemia is important for both medical and performance reasons.

6.4.2 Education. Health care professionals working with female athletes should be qualified and experienced in the detection, diagnosis and treatment of the female athlete triad and iron deficiency anemia.

Educational programs for athletes and coaches focused on prevention of the female athlete triad and iron deficiency anemia are recommended to decrease the incidence of these health concerns, to maximize athletic performance and to ensure that female athletes enjoy the benefits of sport participation.

7. TECHNOLOGY

7.1 Community of practice/training

The Internet represents an ideal platform for the establishment of a portal/community where medical and scientific experts can share information for the purpose of enhancing best clinical practice and advancing science related to PHE. It can also act as a forum for ongoing education and training of the medical, administrative and athlete participants.

7.2 Data collection

Medical/research community portal. The PHE research project may contain a Web Portal where the sports medicine and scientific community with an interest in PHE can access, review and comment on the latest information, results and progress of this PHE research project.

Data collection tools. The questionnaire components of the PHE facilitate the standardization of the PHE and permits analysis of the sensitivity and specificity of the questions asked. Where practical, the questionnaire components can be completed via the Internet provided any such Internet based programs conform to the recognized

technology industry standards for network security and authentication, and that they are in compliance with the local guidelines and/or standards for the collection and storage of Personal Health Information. An internet based version of the PHE Questionnaire would be time- and cost-efficient incremental step in the evolution of the PHE, enabling the participation of athletes, medical professionals and administrators from jurisdictions with limited facilities and budgets. An Internet based Questionnaire application provides an efficient means to enforce data collection standards across multiple input points, therefore improving the accuracy of any research outcomes.

7.3 Data mining

Web based data repositories present an ideal environment within which de-identified aggregate PHE data can be mined and analyzed, thereby facilitating the ongoing improvement of best practices related to the PHE. In all cases the security and privacy of this personal health data is of the utmost importance.

Where software tools are employed to facilitate the input and/or collection of athlete data the following principles should be considered:

Data security and privacy.

- Data processing should be in keeping with good faith efforts
- Data processing should be proportional (only collect the data that is needed)
- Data should be processed only for the purposes indicated and agreed to by the athlete and/or his/her legal representative
- The Data should be precise
- The Data should be protected against any form of unauthorized processing and provide full and complete audit trail of all transactions related to the Data
- The Data should be legitimate
- The Data should be transparent to the owner (the athlete maintains access)
- Furthermore any organization implementing PHE should adopt best practices with respect to human behavior and the safeguarding of all personal medical data.

8. PHE FORM

A final objective was to provide a practical PHE Form that could be used by various groups and form a starting point for further evaluation. Testing and standardization in medicine is not possible if we do not begin somewhere. The first step in creating such a form was to collect existing forms, including those in widespread use. These included the FIFA Pre Competition Medical Assessment (PCMA), the Pre-Participation Physical Evaluation form (Matheson 2005), the electronic Pre-Participation Evaluation (Meeuwisse 2003), the National Hockey League Pre-Participation Medical Evaluation form, plus specialized forms including the American Heart Association recommendations (Maron, 2007), the Lausanne Recommendations (Bille 2006), plus the items outlined in the text of this manuscript. The second step was to combine these into a master set of

questions/items that was inclusive. This was circulated to the authors for review.

The third step will be to go through refinement in the future. This should be done on the basis of scientific evidence, which will come through evaluation with prospective data collection in a variety of sporting populations.

9. SCIENTIFIC ADVISORS

The IOC now has high-level scientific advisors who are capable of monitoring new developments in the field of PHE, and of advising the IOC in relation to the use and abuse of PHE. These advisors will help ensure that athletes and coaches receive the benefits of these developments in improving their ability to prevent injury, and to enhance therapy if needed. The IOC will follow this field and hold a new conference in 2011.

10. FUTURE DIRECTIONS

It is recommended that PHEs be set up and conducted as research projects. Presently, the decision to implement a compulsory PHE must be taken by the International Federations. It must be in compliance with ethical and legal requirements applicable to biomedical research involving human beings. Project findings should be shared and used by the medical and scientific community to further develop and improve best practices. In particular, such research should be conducted “in accordance with the recognized principles of research ethics, in particular the Helsinki Declaration adopted by the World Medical Association (Edinburgh, 2000), and the applicable laws” (Article 7.5 of the Olympic Movement Medical Code).

Governing sports bodies (National Olympic Committees and International Federations) are encouraged to support research activities to provide sport discipline specific scientific and medical evidence as related to the improvement and application of PHE.

APPENDIX 1. ATHLETE PERIODIC HEALTH EVALUATION (PHE) FORM.

MEDICAL HISTORY

Demographic

Personal Information

Last Name _____ First Name _____
 Address: Street _____ City _____ Region _____
 Post Code _____ Country _____
 Preferred Language: _____
 Birthdate: yyyy ____/mm ____/dd ____
 Sex (M/F): _____
 Phone: Home _____ Mobile _____
 Emergency Contact 1: Name _____ Relationship _____ Phone _____
 Emergency Contact 2: Name _____ Relationship _____ Phone _____
 Health Care Insurance (company number): _____
 Family Physician (name, phone number): _____

Background

The following questions ask for information regarding your personal background

What is your main sport? (sport, event/position): _____

Have you participated in other sports in the past (include those sports you have done competitively)? No ☐ Yes ☐ _____

What is your ethnic origin?: _____

Do you have any religious convictions that could affect your medical treatment? No ☐ Yes ☐

When was the last time you had a complete physical examination?: _____

Have you ever failed a pre-participation examination for sports, or has your doctor ever stopped you from participating in sports for any reason? No ☐ Yes ☐

In total, how many days have you missed practice or competition in the past year because of injury or illness?: _____

Heart

Have you ever had any of the following heart or circulation related problems?:

Chest pain, discomfort, tightness or pressure with exercise? No ☐ Yes ☐

Unexplained fainting or near fainting or passed out for no reason DURING or AFTER exercise? No ☐ Yes ☐

Excessive or unexplained shortness of breath, lightheaded, or fatigue with exercise? No ☐ Yes ☐

Do you get more tired or short of breath more quickly than your friends during exercise? No ☐ Yes ☐

Does your heart race or skip beats (irregular beats) during exercise? No ☐ Yes ☐

Heart murmur, high blood pressure, high cholesterol, heart infection or inflammation, rheumatic fever, heart valve problems, or any other heart related problem? No ☐ Yes ☐

Have you ever had an unexplained seizure? No ☐ Yes ☐

Any tests for your heart (for example, ECG or EKG, echocardiogram)? No ☐ Yes ☐

Breathing

Have you ever had any of the following respiratory or breathing problems:

Do you have asthma? No ☐ Yes ☐

Do you have any other symptoms of respiratory (lung) disease including, wheezing, cough, postnasal drip, hay fever, or repeated flu like illness? No ☐ Yes ☐

Do you cough, wheeze or have more difficulty breathing than you should during or after exercise? No ☐ Yes ☐

Have you ever used asthma medication (such as an inhaler)? No ☐ Yes ☐

Have you ever had bronchitis, pneumonia, tuberculosis, cystic fibrosis or other respiratory or other breathing problem? No ☐ Yes ☐

Heat

The following questions are about exercise in the heat:

Have you ever become ill while exercising in the heat? No ☐ Yes ☐

Have you ever been diagnosed with heat exhaustion, heat stroke or hyperthermia? No ☐ Yes ☐

Do you get frequent muscle cramps while exercising? No ☐ Yes ☐

Have you ever had electrolyte (salt) or fluid imbalance? No ☐ Yes ☐

Medical

Do you have any ongoing medical conditions or illness? No ☐ Yes ☐

Do you have, or have you ever had any symptoms of medical problems such as:

Infections mononucleosis (**mono**), flu like symptoms or viral illness within the past month? No ☐ Yes ☐

Disease of the **ears** (infections, hearing loss, pain), **nose** (sneezing, itchy nose, sinusitis, blocked nose) or **throat** (sore throat, hoarse voice, swollen glands in the neck)? No ☐ Yes ☐

Blood disorders such as anemia, low iron stores, sickle cell trait or sickle cell disease, abnormal bleeding or clotting disorder, blood clot (embolus), or other blood disorder? No ☐ Yes ☐

Immune system including current infections, recurrent infections, HIV/AIDS, leukemia, or are you using any immunosuppressive medication? No ☐ Yes ☐

Skin problems such as rashes, infections (fungus, herpes, MRSA) or other skin problems? No ☐ Yes ☐

Kidney or bladder disease, blood in the urine, loin pain, kidney stones, frequent urination, or burning during urination? No ☐ Yes ☐

Gastrointestinal disease including heartburn, nausea, vomiting, abdominal pain, weight loss or gain (> 5kg), a change in bowel habits, chronic diarrhea, blood in the stools, or past history of liver, pancreatic or gallbladder disease? No ☐ Yes ☐

Nervous system including past history of stroke or transient ischaemic attack (TIA), frequent or severe headaches, dizziness, blackouts, epilepsy, depression, anxiety attacks, muscle weakness, nerve tingling, loss of sensation, muscle cramps, or chronic fatigue? No ☐ Yes ☐

Metabolic or hormonal disease including diabetes mellitus, thyroid gland disorders, or hypoglycemia (low blood sugar)? No ☐ Yes ☐

Infections such as meningitis, hepatitis (jaundice), or chicken pox? No ☐ Yes ☐

Arthritis or joint pain, swelling and redness not related to injury? No ☐ Yes ☐

Were you born without, or are you **missing** a kidney, an eye or any other organ? No ☐ Yes ☐

An injury to the any internal organs such as your liver, spleen, kidney(s) or lung?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Have you ever had surgery ? (explain)	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Do you get motion sickness (car, air or sea sickness)?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Do you have any other medical problems?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Family		
Do any of your family members have a history of any of the following conditions (in male relatives < 55 years, female relatives < 65 years):		
Sudden death for no apparent reason (including drowning, unexplained car accident, or sudden infant death syndrome)?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Unexplained fainting, seizures, or near drowning?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Died before age 50 due to heart disease?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Disability or symptoms from heart disease before age 50?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Other heart problems including electrical problems (arrhythmia) or heart enlargement, cardiomyopathy, heart surgery, pacemaker or defibrillator?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
High blood pressure or high blood cholesterol?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Marfan's Syndrome?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Bleeding disorder, Sickle cell trait or sickle cell disease?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Tuberculosis or Hepatitis?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Anaesthetic reaction or problem?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Other condition such as stroke, diabetes, cancer, arthritis (describe)?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Are you unsure of your family history?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Medications		
The following questions are about medications and supplements you are taking, or have taken in the past month:		
Medications that have been prescribed by a doctor (include insulin, allergy shots or pills, sleeping pills, anti-inflammatory medications etc.)?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Non-prescription medications (include pain killers, anti-inflammatories, etc.)?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Vitamin or mineral supplements or herbal medicines?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Other substance to improve your athletic performance (include substances like creatine, weight gain products, amino acids, etc.)?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Have you ever been offered or encouraged to use banned performance enhancing drugs ?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Allergies		
Do you have any allergies to:		
Medication?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Anything else, such as foods, pollens, stinging insects, any plant material or any animal material?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Immunization		
Indicate which immunizations you have received:		
Tetanus / Diphtheria (Td or Tdap)? No <input type="checkbox"/> Yes <input type="checkbox"/> Last shot? _____		
Measles / Mumps / Rubella (2 shots)? No <input type="checkbox"/> Yes <input type="checkbox"/>		
Chicken Pox (Varicella)? No <input type="checkbox"/> Yes <input type="checkbox"/>		
Meningitis (Menimune or Menactra)? No <input type="checkbox"/> Yes <input type="checkbox"/>		
Hepatitis A (2 shots)? No <input type="checkbox"/> Yes <input type="checkbox"/>		
Hepatitis B (3 shots)? No <input type="checkbox"/> Yes <input type="checkbox"/>		
Malaria? No <input type="checkbox"/> Yes <input type="checkbox"/>		
Have you had a TB Test (PPD)? No <input type="checkbox"/> Yes <input type="checkbox"/> Result? _____		
Have you had any other immunizations? No <input type="checkbox"/> Yes <input type="checkbox"/> Explain: _____		
Female		
These questions are for females only:		
Have you ever had a menstrual period?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
What was your age at your first menstrual period?: _____		
Do you have regular menstrual cycles?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
How many menstrual cycles did you have in the last year?: _____		
When was your most recent menstrual period?: _____		
Have you had a stress fracture in the past?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Have you ever been identified as having a problem with your bones such as low bone density (osteopenia or osteoporosis)?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Are you presently taking any female hormones (estrogen, progesterone, birth control pills)?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Have you ever had a sexually transmitted disease such as gonorrhea, syphilis, venereal warts, chlamydia or other infection?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Male		
These questions are for males only:		
Do you have two normal testicles?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Have you ever had a hernia or swelling around the testicle (varicocele, hydrocele)?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Have you ever had an injury to a testicle?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Have you ever had surgery for an undescended testicle, testicular injury or problem?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Have you ever had a sexually transmitted disease such as gonorrhea, syphilis, venereal warts, chlamydia or other infection?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Head & Neck		
Have you ever had any of the following problems related to your head or neck?:		
Eye injury, or other problems with your vision?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Headaches with exercise?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Have you ever had numbness, tingling or weakness in your arms and legs or been unable to move your arms or legs after being hit or falling?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Do you have, or have you been x-rayed for, neck (atlantoaxial) instability?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Have you had an injury to your teeth?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Do you have any other decayed, missing or filled teeth?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Do you have a dental prosthesis or appliance?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Have you had your wisdom teeth removed?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Injury		
Have you ever had an injury to your face, head, skull or brain (including a concussion, confusion, memory loss or		

headache from a hit to your head, having your "bell rung" or getting "dinged")?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Have you had a problem or an injury like a sprain, strain, muscle or ligament tear, or tendonitis, broken bone, stress fracture or joint injury (that caused you to miss a practice or competition) to any of the following areas of your body?		
Neck or spine (including a "stinger," or "whiplash,")	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Upper back (thoracic spine)	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Lower back (lumbar spine)	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Chest and ribs	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Shoulder area (including collar bone)	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Upper arm	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Elbow	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Lower arm (forearm)	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Wrist	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Hand or fingers	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Pelvis, groin or hip (including sports hernia)	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Thigh (including hamstrings and quadriceps)	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Knee	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Lower leg (calf or shin)	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Ankle	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Foot, heel or toes	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Other		
Tests - If not already mentioned above, have you had any other tests, for any injury or condition including blood tests, X-rays, MRI, CT scan, Bone scan, Ultrasound, Electroencephalogram (EEG), Electromyogram (EMG), Nerve conduction studies (NCS), Electrocardiogram (ECG/EKG), Echocardiogram (Echo), Exercise stress test or other tests?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Treatment - If not already mentioned above, have you ever received any of the following treatments for any condition?		
Surgery?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Been prescribed a brace, sling, cast, walking boot, orthotic, crutches or other appliance?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Cortisone injection?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Been prescribed other rehabilitation or therapy ?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Have you ever spent the night in a hospital or been admitted to a hospital as an inpatient or outpatient?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Been referred to a medical specialist (cardiologist, neurologist or other medical person) for any condition not already mentioned?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Equipment		
Do you wear eye glasses or contact lenses?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Are you currently using any of the following protective equipment?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Do you use protective eyewear?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Special equipment (pads, braces, etc.)?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Mouth guard for sports?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
If you wear a helmet for sports, how old is it?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Nutrition		
The following questions are about nutrition:		
Do you worry about your weight or body composition?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Are you satisfied with your eating pattern?	No <input type="checkbox"/>	Yes <input type="checkbox"/>
Are you a vegetarian?	No <input type="checkbox"/>	Yes <input type="checkbox"/>

Discuss		
Do you have any other concerns that you would like to discuss with a doctor?	No <input type="checkbox"/>	Yes <input type="checkbox"/>

Explain "YES" answers here:

I hereby state that, to the best of my knowledge, my answers to the above questions are complete and correct.

Signature of athlete: _____

Signature of parents or legal representative (when needed): _____ Date _____

PHYSICAL EXAMINATION

Date of Examination: _____

Medical

	NORMAL	ABNORMAL (specify)
Appearance		
Eyes/ears/nose/throat		
Hearing		
Lymph nodes		
Heart		
Rhythm		
Heart sounds / murmurs in supine and standing		
Peripheral oedema		
Physical stigmata of Marfan's syndrome		
Blood vessels		
Peripheral pulses		
Delay in femoral pulses		
Vascular bruits (femoral)		
Varicose veins		
Blood Pressure in Sitting Position (after 5 minutes rest)		
Right arm		
Left arm		
Heart rate (after 5 Minutes rest)		
Lungs		
Abdomen		
Genitourinary (males only)		
Skin		
Eyes		
visual acuity (corrected/uncorrected)		
equal pupils		

Dental

DMF Index = Number of decayed, missing or filled teeth : _____

Oral Hygiene assessment: ☐ Good ☐ Fair ☐ Poor

Visible Oral Infection: ☐ No ☐ Yes

Presence of Worn, Broken or Loose/Mobile teeth: ☐ No ☐ Yes

Dental appliances (bridge, plate, braces or orthodontic appliance): ☐ No ☐ Yes

Musculoskeletal

Neck		
Back		
Shoulder/arm		
Elbow/forearm		
Wrist/hand/fingers		
Hip/thigh		
Knee		

Leg/ankle

Foot/toes

Investigations

12 Lead ECG

Details:

- ☐ Normal / no changes
☐ Common and training-related ECG changes
☐ UnCommon training-unrelated ECG changes

--

Blood Tests

Other:

Haemoglobin
Haematocrit
Erythrocytes
Thrombocytes
Leukocytes
Ferritin
Sodium
Potassium
Creatinine
Cholesterol (total)
LDL Cholesterol
HDL Cholesterol
Triglycerides
Glucose
C-reactive Protein

Clinical Evaluation Outcome

1 The athlete does not present apparent clinical contraindications to practice the following sport(s) (specify): No • Yes •

If the answer to question 1 is "No", it is recommended that the athlete:

avoids participating:

- in training (explain)

No • Yes •

- in competition (explain)

No • Yes •

respects the following restrictions:

- during training (specify)

No • Yes •

- during competition (specify)

No • Yes •

undergoes further examinations (specify):

Examining physician

Name: _____ Phone Number: _____
Address: _____ Email: _____

APPENDIX 2. CONSENSUS STATEMENT CONTRIBUTORS.

Arne Ljungqvist (Sweden) Peter Jenoure (Switzerland)	Chairman, International Olympic Committee (IOC) Medical Commission Coordinator, Periodic Health Evaluation Associate Professor of Sports Medicine Basel and Neuchâtel Member of the IOC Medical & Scientific Group Member Interfederal Commission FIMS
